

Get the Data Into a Database

Our first hands-on task: get the data and put it in a real database.

1

Step 1 — Read & understand

- Open the PDF I sent (Olist_Dataset_Introduction.pdf) — it has the full description of the data
- Go to the Kaggle link inside it and read the dataset page
- Understand the tables and how they relate to each other (order_id, customer_id, product_id, seller_id)
- **Understand the problem we are solving: predict if an order will be delivered late or on time**
- Check what other people did with this data (public notebooks) — for ideas, not for copying

2

Step 2 — Download & ingest

- Download the CSV files from Kaggle
- Load them into a relational database — PostgreSQL, or any DB you prefer
- Use the links I sent about database foundations and Docker basics — study them well, you will need them all along the track

3

Step 3 — Test it

- Open a notebook or your terminal and connect to the database
- Read the tables, run some queries, try a join between two tables
- Make sure everything works before you stop

Done when

- ✓ The database is running locally with the data inside
- ✓ You can query the tables and join them
- ✓ You understand the tables and the relations between them
- ✓ You understand the problem we are trying to solve

Notes

- No EDA needed now — that comes in a later task. If you want to explore, go ahead, but it is optional
- Take your time with Docker and SQL, this is the foundation of everything after it

Good luck guys!
